

Auto Ticket Classification using Flow Designer

Solution Requirements (Functional & Non-Functional Specifications)

TEAM ID	DATE	PLATFORM	MAXIMUM MARKS
SWTID-2026-8437	01 October 2026	ServiceNow Cloud	4 Marks

Executive Summary: This document outlines the Functional and Non-Functional Requirements for automating incident ticket categorization and routing within ServiceNow using Flow Designer. The solution focuses on a robust, low-code/no-code keyword-driven rules engine that accelerates ticket processing and eliminates manual triage overhead.

Functional Requirements

FR No.	Functional Requirement (Epic)	Sub Requirement (Story / Sub-Task)
FR-1	Incident Trigger	Start the Flow Designer flow automatically whenever a new incident record is created in ServiceNow.
FR-2	Incident Data Capture	Extract and read the incident Short Description and Description fields for text processing.
FR-3	Keyword Analysis	Evaluate incident text against predefined keyword sets related to standard IT and operational issues.
FR-4	Automatic Classification	Dynamically assign the appropriate incident category based on matching keyword rules.
FR-5	Ticket Routing	Utilize the resulting classification to route and assign the incident to the appropriate IT support group.
FR-6	No-Code Maintenance	Allow authorized administrators to modify keyword conditions in Flow Designer without writing custom code.

Non-Functional Requirements

NFR No.	Requirement Area	Description & Operational Quality
NFR-1	Usability	The Flow Designer visual interface and rule configuration must remain intuitive and simple for authorized administrators to inspect, modify, and maintain.
NFR-2	Security	Enforce strict Role-Based Access Control (RBAC) so only authorized ServiceNow administrators can configure flows or alter classification rules.
NFR-3	Reliability	The automated flow must consistently execute on 100% of newly created incidents and accurately apply updates when keyword conditions are met.
NFR-4	Performance	Classification rules must evaluate in real time during incident creation, avoiding queue delays or the latency of external third-party integrations.
